

Railo allows you to define several settings you normally make in the administrator inside the `Application.cfc` or in the `CFAPPLICATION` tag as an attribute.

With Railo 3.3 the local mode can be defined inside the `Application.cfc` `autoinclude` component. The local mode defines how uninitialized variables will be treated.

The local mode in Railo allows you to define how variables inside functions are treated. The setting allows two different statuses:

```
this.localmode="always">
```

This setting puts uninitialized variables inside a `function` body into the local scope upon definition.

```
this.localmode="never">
```

This is the `default` setting and places a variable into the variables scope `if` it hasn't been found in any of the local scopes.

You also have the possibility of defining the session type (`cfml|j2ee`) within your application.

Example `Application.cfc`

```
this.sessionType="j2ee" ...>
```

Example `Application.cfm`

```
sessionType="j2ee" ...>
```
