

Preventing the Flex integration in Railo to create unnecessary WEB-INF directories

For the flex configuration there are some files that are necessary for each web context. They are usually generated inside the webroot in a folder called WEB-INF/flex. Up until Railo version 3.3 there was no possibility of changing this directory. It should be possible to use Railo without Flex and therefore it would be good if one can get rid of this directory. The way to do this is to edit the file railo-[web|server].xml[.cfm] and define the following inside the tag flex:

```
configuration="xml|manual" ...>
```

```
xml = auto-deploy the configuration as xml (default)
```

```
manual = no deployment at all, user has to add the configuration manually
```
